Abstract

We present [OpenBiodiv](#) - an implementation of the Open Biodiversity Knowledge Management System.

The need for an integrated information system serving the needs of the biodiversity community can be dated at least as far back as the sanctioning of the [Bouchout declaration](#) in 2007. The Bouchout declaration proposes to make biodiversity knowledge freely available as Linked Open Data (LOD)*1. At TDWG2016 Fig. 1) we presented the prototype of the system - then called Open Biodiversity Knowledge Management System (OBKMS). The specification and design of OpenBiodiv was outlined by Senderov and Penev (2016) and in this talk we would like to showcase its pilot. We believe OpenBiodiv is possibly the first pilot-stage implementation of a semantic system running on top of the biodiversity knowledge graph.

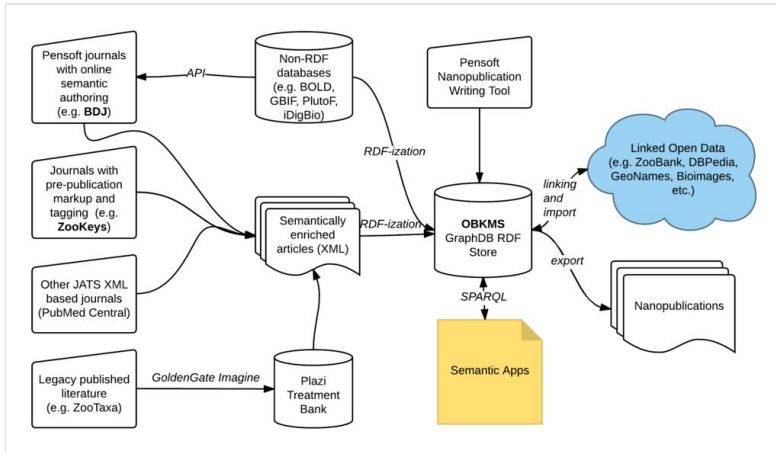

Figure 1.

High-level Architecture of OpenBiodiv.

OpenBiodiv has several components:

1. OpenBiodiv ontology: general data model allowing the extraction of biodiversity knowledge from taxonomic articles or from databases such as GBIF. The ontology (in preparation, Journal of Biomedical Semantics, [available on GitHub](#)) incorporates several pre-existing models: Darwin-SW (Baskauf and Webb 2016), SPAR (Peroni 2014), [Treatment Ontology](#), and several others. It defines classes, properties, and rules allowing to interlink these disparate ontologies and to create a LOD of biodiversity knowledge. New is the Taxonomic Name Usage class, accompanied by a Vocabulary of Taxonomic Statuses (created via an analysis of 4,000 Pensoft articles) allowing for the automated inference of the taxonomic status of Latinized scientific names. The ontology allows for multiple backbone taxonomies via the introduction of a Taxon Concept class (equivalent to DarwinCore Taxon) and Taxon Concept Labels as a subclass of biological name.
2. The Biodiversity Knowledge Graph - a LOD dataset of information extracted from taxonomic literature and databases. In practice, it has realized part of what has been proposed during [pro-iBiosphere](#) and later discussed by Page (2016). Its main resources are articles, sub-article components (tables, figures, treatments, references), author names, institution names, geographical locations, biological names, taxon concepts, and occurrences. Authors have been disambiguated via their affiliation with the use of fuzzy-logic based on the [GraphDB Lucene connector](#). The graph interlinks: (1) Prospectively published literature via [Pensoft Publishers](#). (2) Legacy literature via [Plazi](#). (3) Well-known resources such as geographical places or institutions via [DBPedia](#). (4) GBIF's backbone taxonomy as a default but not preferential hierarchy of taxon concepts. (5) [OpenBiodiv](#) id's are matched to nomenclator id's (e.g. [ZooBank](#)) whenever possible. Names form two networks in the graph: (1) A directed-acyclical graph (DAG) of supercedence that can be

followed to the corresponding sinks to infer the currently applicable scientific name for a given taxon. (2) A network of bi-directional relations indicating the relatedness of names. These names may be compared to the related names inferred on the basis of distributional semantics by the co-organizers of this workshop (Nguyen et al. 2017).

3. `ropenbio`: an R package for RDF*2-ization of biodiversity information resources according to the OpenBiodiv ontology. It will be submitted to the rOpenSci project. While many of its high-level functions are specific to OpenBiodiv, the low-level functions, and its RDF-ization framework can be used for any R-based RDF-ization effort.
4. OpenBiodiv.net: a front-end of the system allowing users to run low-level SPARQL queries as well to use an extensible set of semantic apps running on top of the Biodiversity Knowledge Graph.

The talk will showcase the progress from prototype to pilot stage of the system since TDWG2016. It will focus on the new features and about the web UI allowing researchers and other interested parties to already use the system. We will discuss several possible scenarios including semantic search and finding related names.

Keywords

Linked Open Data, R package, RDF, SPARQL, Biodiversity Knowledge Graph, Semantic web, Semantic publishing, inference
